Finding all Local Models in Parallel: Multi-Objective SVM
Motivation

- Model = Global Model + Local Model(s) + Noise
- SVM can find both the global and the local models
- Conflicting criteria: training error and model complexity
- Users have to specify a weighting factor $C$ for a trade-off
- Local models: those for higher weights on training error

Solution

Embed multi-objective evolutionary algorithms instead of the quadratic programming approach into SVM.
Motivation

- Model = Global Model + Local Model(s) + Noise
- SVM can find both the global and the local models
  - Conflicting criteria: training error and model complexity
  - Users have to specify a weighting factor C for a trade-off
  - Local models: those for higher weights on training error

Solution

Embed multi-objective evolutionary algorithms instead of the quadratic programming approach into SVM.
Motivation

- Model = Global Model + Local Model(s) + Noise
- SVM can find both the global and the local models
- Conflicting criteria: training error and model complexity
  - Users have to specify a weighting factor C for a trade-off
  - Local models: those for higher weights on training error

Solution

Embed multi-objective evolutionary algorithms instead of the quadratic programming approach into SVM.
Motivation

- Model = Global Model + Local Model(s) + Noise
- SVM can find both the global and the local models
- Conflicting criteria: training error and model complexity
- Users have to specify a weighting factor C for a trade-off
- Local models: those for higher weights on training error

Solution

Embed multi-objective evolutionary algorithms instead of the quadratic programming approach into SVM.
### Motivation

- Model = Global Model + Local Model(s) + Noise
- SVM can find both the global and the local models
- Conflicting criteria: training error and model complexity
- Users have to specify a weighting factor C for a trade-off
- Local models: those for higher weights on training error

### Solution

Embed multi-objective evolutionary algorithms instead of the quadratic programming approach into SVM.
Motivation

- Model = Global Model + Local Model(s) + Noise
- SVM can find both the global and the local models
- Conflicting criteria: training error and model complexity
- Users have to specify a weighting factor C for a trade-off
- Local models: those for higher weights on training error

Solution

Embed multi-objective evolutionary algorithms instead of the quadratic programming approach into SVM.
The result of multi-objective optimization is not a single solution but a set of solutions (Pareto set). These solutions correspond to the optimal solutions for all possible weightings for both criteria.

**Figure:** The Pareto-optimal solutions for two competing criteria.
The Primal SVM Problem

The basic form of the primal SVM optimization problem is the following:

\[
\text{minimize} \quad \frac{1}{2} \|w\|^2 + C \sum_{i=1}^{n} \xi_i
\]
\[
\text{subject to } \forall i : y_i (\langle w, x_i \rangle + b) \geq 1 - \xi_i
\]
and \( \forall i : \xi_i \geq 0 \).

Weighting Factor

The parameter \( C \) is a user defined weight for the both conflicting parts of the optimization criterion.
The Primal SVM Problem

The basic form of the primal SVM optimization problem is the following:

\[
\text{minimize } \frac{1}{2} \|w\|^2 + C \sum_{i=1}^{n} \xi_i \\
\text{subject to } \forall i : y_i (\langle w, x_i \rangle + b) \geq 1 - \xi_i \\
\text{and } \forall i : \xi_i \geq 0.
\]

Weighting Factor

The parameter \( C \) is a user defined weight for the both conflicting parts of the optimization criterion.
Multiple Conflicting Objectives

- EA inside SVM allows for a straightforward application of multi-objective selection schemes
- We divide the criteria of the primal SVM optimization problem into two optimization targets while the weighting factor C can be omitted

Goal

Transform both objectives into their dual form in order to allow the efficient optimization of the problems including the usage of kernel functions.
Multiple Conflicting Objectives

- EA inside SVM allows for a straightforward application of multi-objective selection schemes
- We divide the criteria of the primal SVM optimization problem into two optimization targets while the weighting factor C can be omitted

**Goal**

Transform both objectives into their dual form in order to allow the efficient optimization of the problems including the usage of kernel functions.
Multiple Conflicting Objectives

- EA inside SVM allows for a straightforward application of multi-objective selection schemes
- We divide the criteria of the primal SVM optimization problem into two optimization targets while the weighting factor C can be omitted

Goal
Transform both objectives into their dual form in order to allow the efficient optimization of the problems including the usage of kernel functions.
Multiple Conflicting Objectives

**Primal Objective 1**

\[
\text{minimize } \frac{1}{2} \|w\|^2 \\
\text{subject to } \forall i : y_i (\langle w, x_i \rangle + b) \geq 1 - \xi_i \\
\text{and } \forall i : \xi_i \geq 0
\]

**Primal Objective 2**

\[
\text{minimize } \sum_{i=1}^{n} \xi_i \\
\text{subject to } \forall i : y_i (\langle w, x_i \rangle + b) \geq 1 - \xi_i \\
\text{and } \forall i : \xi_i \geq 0.
\]
Objective 1: Maximizing the Margin

- Introduce positive Lagrange multipliers $\alpha$ for the first set of inequality constraints and multipliers $\beta$ for the second set of inequality constraints:

$$L_p^{(1)} = \frac{1}{2}||w||^2 - \sum_{i=1}^{n} \alpha_i (y_i (\langle w, x_i \rangle + b) + \xi_i - 1) - \sum_{i=1}^{n} \beta_i \xi_i$$

- Set the derivatives to 0:

$$\frac{\partial L_p^{(1)}}{\partial w}(w, b, \xi, \alpha, \beta) = w - \sum_{i=1}^{n} y_i \alpha_i x_i = 0,$$

$$\frac{\partial L_p^{(1)}}{\partial b}(w, b, \xi, \alpha, \beta) = \sum_{i=1}^{n} \alpha_i y_i = 0,$$

$$\frac{\partial L_p^{(1)}}{\partial \xi_i}(w, b, \xi, \alpha, \beta) = -\alpha_i - \beta_i = 0$$
Plugging the Derivatives into the Primal

- Plugging the derivatives into the primal objective function $L_p^{(1)}$ delivers

$$L_p^{(1)} = \frac{1}{2} \|w\|^2 - \sum_{i=1}^{n} -\alpha_i y_i \left\langle \sum_{j=1}^{n} \alpha_j y_j x_j, x_i \right\rangle + \sum_{i=1}^{n} \alpha_i$$

$$= \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} \alpha_i \alpha_j y_i y_j \left\langle x_i, x_j \right\rangle$$

- The Wolfe dual must be maximized leading to the first objective of the multi-objective SVM
- Result is very similar to the dual SVM problem stated above but without the upper bound $C$ for the $\alpha_i$
The First Objective of the MO-SVM

First Objective

The first SVM objective (maximize margin) is defined as:

\[
\begin{align*}
\text{maximize} & \quad \sum_{i=1}^{n} \alpha_i - \frac{1}{2} \sum_{i=1}^{n} \sum_{j=1}^{n} y_i y_j \alpha_i \alpha_j k(x_i, x_j) \\
\text{subject to} & \quad \alpha_i \geq 0 \text{ for all } i = 1, \ldots, n \\
\text{and} & \quad \sum_{i=1}^{n} \alpha_i y_i = 0
\end{align*}
\]
Objective 2: Minimize Training Errors

- We again add positive Lagrange multipliers $\alpha$ and $\beta$:

$$L_p^{(2)} = \sum_{i=1}^{n} \xi_i - \sum_{i=1}^{n} \alpha_i ((y_i \langle w, x_i \rangle + b) + \xi_i - 1) - \sum_{i=1}^{n} \beta_i \xi_i$$

- Setting the derivatives to 0 leads to slightly different conditions on the derivatives of $L_p^{(2)}$:

$$\frac{\partial L_p^{(2)}}{\partial w}(w, b, \xi, \alpha, \beta) = -\sum_{i=1}^{n} y_i \alpha_i x_i = 0,$$

$$\frac{\partial L_p^{(2)}}{\partial b}(w, b, \xi, \alpha, \beta) = \sum_{i=1}^{n} \alpha_i y_i = 0,$$

$$\frac{\partial L_p^{(2)}}{\partial \xi_i}(w, b, \xi, \alpha, \beta) = 1 - \alpha_i - \beta_i = 0$$
Plugging the Derivatives into the Primal

- **Plugging the derivatives** into the \( L_p^{(2)} \) cancels out most terms:

\[
L_p^{(2)} = \sum_{i=1}^{n} \xi_i - \sum_{i=1}^{n} \alpha_i \xi_i + \sum_{i=1}^{n} \alpha_i - \sum_{i=1}^{n} \beta_i \xi_i
\]

- Together with the third derivative we can replace the \( \beta_i \) by \( 1 - \alpha_i \) leading to

\[
L_p^{(2)} = \sum_{i=1}^{n} \alpha_i \xi_i - \sum_{i=1}^{n} \alpha_i \xi_i + \sum_{i=1}^{n} \alpha_i
\]

\[
L_p^{(2)} = \sum_{i=1}^{n} \alpha_i
\]

- **Maximizing** the Wolfe dual leads to the second objective of the multi-objective SVM
The Second Objective of the MO-SVM

Second Objective

The second SVM objective (minimize error) is defined as:

\[
\text{maximize } \sum_{i=1}^{n} \alpha_i \\
\text{subject to } \alpha_i \geq 0 \text{ for all } i = 1, \ldots, n \\
\text{and } \sum_{i=1}^{n} \alpha_i y_i = 0
\]
Used Objectives

Set of all Objectives

Maximize the terms

\[- \sum_{i=1}^{n} \sum_{j=1}^{n} y_i y_j \alpha_i \alpha_j k(x_i, x_j),\]

and \[\sum_{i=1}^{n} \alpha_i\]

subject to \(\alpha_i \geq 0\) for all \(i = 1, \ldots, n\)

The result will be a Pareto front showing all models which are optimal for all possible weightings between both criteria.

Results

Figure: The results for all data sets. The left plot for each dataset shows the Pareto front delivered by the multi-objective SVM proposed in this paper (x: margin size, y: training error). The right plot shows the training (+) and testing (×) errors (on a hold-out set of 20%) for all individuals of the resulting Pareto fronts (x: margin size, y: generalization error).

Finding all Local Models in Parallel: Multi-Objective SVM
From Global to Local Models – Best Generalization
From Global to Local Models – Lowest Training Error
Main Advantage of MO-SVM

- The generalization ability plotted on the right sides clearly shows the location where overfitting occurs.
- Please note that these plots could also be generated for usual SVM by iteratively applying the learner for different parameter settings but . . .
- . . . this will need one learning run for each possible value of C!

Full Knowledge in One Single Run!

The MO-SVM approach has the advantage that all models are calculated in one single run which is far less time-consuming.

The MO-SVM approach has the advantage that all models are calculated in one single run which is far less time-consuming.
Conclusion

- Trade-off between training error and model complexity is now explicitly stated
- The optimization problem of SVM is divided in two parts and both parts are transformed into their dual form
- The optional usage of a hold-out set is suggested in order to guide the user for the final selection of a solution
- All information from the most global to the most local models is gathered in a single run!
Conclusion

- Trade-off between training error and model complexity is now explicitly stated.
